

1. LLM Workflow Breakdown Example

Intro

This example shows how the **LLM INQUISITOR METHODOLOGY** works in practice. The full methodology explains how to evaluate model behaviour in real workflows by applying tasks, observing how the model responds, and deciding whether to continue, change conditions, or stop when further interaction will not reveal anything new. This example gives a simple demonstration. For the full method, see the main documentation.

Step 1: Baseline

You ask: “Summarise this short article about renewable energy.”

The model gives a clean, accurate summary.

Step 2: Slightly harder

You ask: “Rewrite it for a policymaker but keep the technical accuracy.”

The model still performs well.

Step 3: Conflicting constraints

You ask it to:

- keep all technical terms
- remove policy language
- make it suitable for a 12 year old
- do not shorten it

The model:

- shortens the text
- removes technical terms
- contradicts itself

What this shows

When instructions pull in different directions, the model tends to:

- drop constraints
- oversimplify
- ignore parts of the request

At this point, the evaluator decides whether continuing will reveal anything useful. If the behaviour is already fully understood, the evaluation stops. If recovery or further degradation might provide more insight, the evaluation continues.
