

2. LLM Strengths and Failures Example

Intro

This example shows how the **LLM INQUISITOR METHODOLOGY** reveals strengths early in a workflow and failures later when the task becomes more demanding. The full methodology explains how to observe these changes and decide whether to continue, adjust conditions, or stop when no further insight is likely. This example uses a simple developer friendly scenario.

Step 1: Simple explanation

You ask: “Explain what a bug report is.”

The model gives a correct, stable answer.

Step 2: Slightly deeper

You ask: “Give an example of a bad bug report and explain why it is bad.”

The model gives a coherent explanation.

Step 3: Time pressure and structure

You say: “You have 10 seconds. Rewrite this as a formal bug report with: steps to reproduce expected behaviour actual behaviour severity rating” The model:

- forgets the severity rating
- mixes up expected and actual behaviour
- contradicts itself

Step 4: Longer, more detailed task

You ask: “Expand the fix into a 5 step implementation plan.”

The model:

- loses the original scenario
- adds irrelevant details
- contradicts earlier statements

What this shows

Under pressure or longer tasks, the model often:

- loses context
- contradicts itself
- generalises too much
- mixes unrelated information

The evaluator now decides whether more interaction will produce additional insight. If the pattern is already clear, the evaluation stops. If recovery, worsening, or oscillation might reveal more, the evaluation continues.
