

LLM INQUISITOR: AI Behaviour Explainer / Reporting Aid For Regular Users

AI systems can fail in different ways when used in real work. These issues aren't always visible during development, and they can seem random when they happen. This page helps you spot the common patterns and describe them clearly so the dev team can understand what went wrong.

What AI failures look like

• It wanders off the task	• It stops following my formatting rules
• It forgets earlier details	• It gets slower or “dumber”
• It makes things up	• It repeats itself
• It stops progressing the task	• It rewrites things unnecessarily

Why this happens

• Too much information → it loses track	• Missing or unclear state → it guesses
• Long tasks → it drifts	• Complex workflows → it drops earlier steps
• Heavy server load → it degrades	• Running too long → it collapses or loops

Common symptom → likely cause

- **Stopped following my formatting rules** → losing track
- **Made things up** → overload or missing state
- **Short/dumb/repetitive output** → server load or collapse
- **Ignored instructions** → context loss
- **Tone/style changed** → drift
- **Slowed down** → server load
- **Repeated itself** → collapse

How to describe what happened

“I was doing <task>. After <time/step>, it started <symptom>. This meant I couldn't complete <workflow>.”

Example: “After about 15 minutes of the report, it stopped following my formatting rules and began making up facts.”
